
Toxic Toledo Air and Titanic Trend Searches: A Tale of Sorrow and Search History Tomorrow

Connor Hoffman, Aaron Turner, Gemma P Truman

Abstract

When it comes to air pollution and internet search trends, it turns out there may be more than meets the eye. In this study, we delve into the connection between air pollution in Toledo and Google searches for the Titanic, aiming to uncover whether there's a deeper relationship hidden beneath the toxic fumes. Using data from the Environmental Protection Agency and Google Trends, our research team sifted through the digital exhaust to uncover a surprising correlation. Strapping on our statistical diving gear, we found a correlation coefficient of 0.8679007 - a figure more majestic than the ship itself - and $p < 0.01$ for the years 2008 to 2023. The results beg the question: Could the smog of Toledo be lifting the search history of a century-old maritime disaster, or are we simply riding a wave of coincidental curiosity? Join us as we navigate these uncharted waters, where the winds of data and the tides of trends collide.

1. Introduction

INTRODUCTION

A wise man once said, "When life gives you lemons, make lemonade. But when life gives you toxic air, you might not want to breathe too deeply." In recent years, the citizens of Toledo, Ohio, have found themselves contending with air pollution levels higher than a skyscraper and more unwelcome than a telemarketer at dinnertime. Simultaneously, the world's populace has increasingly sought solace and answers in the worldwide web, turning to the mighty Google search engine for their daily doses of knowledge, procrastination, and adorable animal videos.

Our study seeks to unravel the peculiar relationship between these two seemingly unrelated phenomena: the foul haze blanketing Toledo's airspace and the soaring search queries related to the infamous Titanic. Our aim? To determine if there exists a discernible correlation between air pollution levels and the public's online intrigue with the ill-fated vessel. While some may dismiss this as a mere flight of fancy, we took our curiosity and sailed headfirst into the tempest of data analytics and statistical examination, intent on navigating the murky waters of correlation with the skill of seasoned navigators.

As we set sail on this unlikely voyage, we invite our fellow researchers and armchair sleuths alike to join us in uncovering the potential connection between

the odorous emissions wafting through Toledo and the steady rise of maritime disaster-related Google searches. Together, we shall venture forth, undeterred by the squalls of skepticism and armed with a hearty blend of data analysis and a dash of whimsy, because, after all, what's science without a bit of adventure? So, fasten your seatbelts, or rather, tie your shoelaces - we're about to embark on a journey more riveting than the sequel to "Fifty Shades of Grey" - except this time, the only shades in question are those of grey smog and blue links on Google search result pages.

2. Literature Review

Research into the connection between air pollution and seemingly unrelated phenomena has yielded both insightful and, dare we say, titanic findings. In their groundbreaking study, Smith and Doe (2015) set sail into the uncharted waters of environmental psychology, examining the impact of air quality on human behavior. Their analysis, while initially focused on the broader spectrum of emotional and cognitive responses, inadvertently brushed against the winds of the internet, hinting at a potential correlation between airborne pollutants and online search patterns.

Smith and Doe's revelation piqued the curiosity of researchers venturing into the realm of digital epidemiology, where Jones (2018) embarked on a quest to unravel the mysteries of online trend tracking. Though Jones did not specifically explore the link between air pollution and maritime disasters, the notion of uncovering hidden connections through internet search history ripples through the annals of cyberspace, much like a discarded chip bag caught in a gust of Toledo's polluted air.

Now, turning our gaze to the literary seas, we espy a veritable fleet of relevant tomes that might buoy our understanding of this peculiar correlation. In "Air Pollution and Its Effects on Human Health" by Lorem and Ipsum (2016), the authors delve into the myriad ways in which air pollution can impact human behavior and well-being, inadvertently setting the stage for considering the potential influence on online activity. Meanwhile, "The Titanic: End of a Dream" by Wyn Craig Wade

(2012) and "Futility, or the Wreck of the Titan" by Morgan Robertson (1898) provide historical context for the enduring allure of Titanic-related searches, shedding light on the timeless fascination with the tragic vessel.

But wait, the plot thickens! A survey of social media posts reveals a trove of curious musings, akin to seagulls circling a digital mariner's tale, hinting at the intriguing intersection of air pollution and search engine queries. One Twitter user, amidst a fog of existential pondering, remarked: "Is the smog making us search for the Titanic, or are we collectively seeking a ship to escape this airpocalypse?" Another mused, "Toledo's air may be murky, but at least our search history is crystal clear - Titanic, Titanic, and more Titanic! Ahoy, online obsessions!"

As we navigate these uncharted waters of academia, it becomes clear that the connection between Toledo's air pollution and the public's fascination with the Titanic is no mere flight of fancy - it's a voyager's delight, replete with unexpected twists and turns that could rival the most dramatic of maritime sagas. So batten down the hatches, fellow scholars, for we are about to embark on an expedition more spirited than a sea shanty and more illuminating than a lighthouse beam cutting through the haze of uncertainty.

3. Methodology

METHODOLOGY

To uncover the mysterious relationship between the air pollution plaguing Toledo and the Google search trends for the Titanic, our research team embarked on a journey rivaling Odysseus' ten-year expedition - albeit with fewer Cyclops encounters and more coffee breaks. Our approach blended the precision of a surgeon's scalpel with the tenacity of a bloodhound on the scent, as we scavenged through a digital jungle for morsels of data gold.

Data Collection and Sources

First, we turned our attention to the Environmental Protection Agency's treasure trove of air quality data. Armed with our trusty spectrometers and metaphorical gas masks, we mined data on various

air pollutants, including but not limited to sulfur dioxide, nitrogen dioxide, and particulate matter. We then combed through the Google Trends platform like detectives on a crime scene, analyzing the search interest for terms related to the Titanic, ensuring we didn't overlook even a speck of digital evidence. Our search terms included "Titanic," "RMS Titanic," "shipwreck," and "unsinkable ship," among others, capturing the full spectrum of Titanic-related inquiries.

Integration and Analysis

Next, we harnessed the power of statistical software akin to alchemists turning lead into gold, merging the disparate datasets into a harmonious symphony of variables. We then performed a rigorous wave of regression analysis, teasing out the subtle correlations between air pollutant levels in Toledo and the ebb and flow of Titanic-themed Google searches. Like seasoned fishermen casting their nets, we sought to capture elusive patterns amid the ever-shifting currents of data, hoping to reel in a catch that would make even Ahab envious.

Timeframe

Our study encompassed a window of data stretching from the year 2008 to 2023 - a period marked by the evolution of both air pollution monitoring techniques and the ebb and flow of internet search habits. Anchoring ourselves in this time frame allowed us to capture the full breadth of digital tides and atmospheric fluctuations, akin to seasoned sailors charting their course through ever-changing storm fronts.

Limitations and Assumptions

It is essential to note the caveats and assumptions that underpin our study, much like the navigational cautions printed on a treasure map. We assumed a linear relationship between air pollution levels and Google search trends, acknowledging that the web of human behavior is as tangled as a sailor's knot after a few too many rounds of grog. Additionally, our reliance on publicly available data entailed the risk of overlooking potential confounding variables, akin to sailing into uncharted waters with only a vague map and a hopeful spirit.

In essence, our methodology fused tenacity with precision and whimsy with rigor, navigating the

whirlpools of digital data and statistical analysis to uncover the potential links between Toledo's air pollution and the captivating lure of the Titanic in the vast sea of web searches.

Now, let's set our sights on the horizon as we delve into the deep waters of our findings - a journey fraught with intrigue, surprise, and perhaps the occasional "I didn't see that one coming" exclamation. Science, after all, is the art of unraveling the unexpected and connecting the unconnected, much like discovering a soggy treasure map in the midst of a howling internet storm. So, secure your proverbial life jackets - we're about to embark on a voyage more daring than Gutenberg's first attempts at software coding. Let's set sail, preferably with a hearty chantey and a side of digital compass - it's going to be a remarkable expedition, indeed.

4. Results

RESULTS

The outcome of our expedition into the hazy realms of air pollution and internet search trends has revealed a correlation coefficient of 0.8679007 between the concentration of air pollutants in Toledo and the frequency of Google searches for the Titanic. This numerical value shines brighter than the Hope Diamond, pointing to a strong positive relationship between these seemingly unconnected phenomena. Not to be outdone, the r-squared value of 0.7532516 further bolsters the evidence for a substantial association, proving that this isn't just a passing cloud of statistical noise.

The figure (Fig. 1) presented below illustrates the robust correlation with a scatterplot that could rival the starry night sky in terms of sheer beauty. The data points align themselves like a constellation of evidence, demonstrating the synchronicity between Toledo's polluted atmosphere and the public's intrigue with the ill-fated ship.

environmental factors and online behavior. It's a reminder that, much like the unpredictable seas, the digital world may hold hidden currents and connections waiting to be uncovered.

So, fellow researchers and enthusiasts, let's batten down the hatches and prepare for further voyages into the delightful choppy waters of correlation and causation. With our curiosity as our compass, who knows what marvels we may yet discover in the digital expanse?

6. Conclusion

As we bid adieu to our expedition through the misty realms of air pollution and internet search trends, we are left with more questions than answers. The strength of the correlation coefficient, as formidable as the iceberg that met the Titanic, suggests a tangible link between Toledo's unhealthy air and heightened public interest in the ill-fated ship. It seems that when Toledo's air quality goes down, the Titanic's search history goes up – a relationship seemingly stranger than fiction, or as we like to call it, "Toxic Toledo meets Titanic Trendmania."

These findings shed light on the curious ways in which environmental factors may influence the collective digital consciousness. Could it be that Toledo's polluted air acts as a not-so-subliminal cue for internet users to embark on a historically themed voyage? Or are we merely witness to a statistical dance of chance, where correlation and causation part ways like ships in the night? The intricacies of this connection are as enthralling as a suspense novel, leaving us on the edge of our seats, eagerly awaiting a sequel.

While our study offers an initial glimpse into this enigmatic association, it also serves as a call to launch further research expeditions. As we navigate the uncharted waters of data analysis and concoct hypotheses as bold as the ship's ill-fated maiden voyage, we must remember that every breakthrough begins with the combination of curiosity, diligence, and the occasional pun. Future endeavors may uncover even more unexpected connections, reminding us that the world of research is not just a sea of data points, but also a treasure trove of unforeseen correlations and delightful surprises.

In conclusion, our findings warrant careful consideration of the potential ripple effect of environmental factors on digital behavior. It's a reminder that behind every trend search lies a story waiting to be unearthed – and who knows, there may be more unexpected connections waiting to be discovered in the vast expanse of search history. As for our study, we firmly assert that no further research is needed in this area unless, of course, you would like to uncover the connection between air pollution in Pittsburgh and searches for "Penguins." But for now, we're setting our sights on new horizons and leaving this peculiar correlation to bask in its own limelight.
